Keywords: Phosphonates Isoxazolidines Triazoles Synthesis Antiviral Cytostatic

ABSTRACT

Azidation (TMSN₃, SnCl₄) of a 9:1 mixture of *trans*- and *cis*-5-acetoxy-2-methylisoxazolidin-3-yl-3-phosphonates at the anomeric carbon atom led to the formation of the equimolar mixture of *cis*- and *trans*-5-azido-2-methylisoxazolidin-3-yl-3-phosphonates, which were efficiently separated. The 1,3-dipolar cycloaddition of pure *trans*- and *cis*-5-azidoisoxazolidin-3-yl-3-phosphonates with selected alkynes gave the respective nucleoside mimetics containing a 1,2,3-triazole linker. The (1,2,3-triazolyl) isoxazolidine phosphonates obtained herein were evaluated in vitro for activity against a variety of DNA and RNA viruses. None of the compounds were endowed with antiviral activity at subtoxic concentrations. Compounds 15f—j and 16f—j were cytostatic in the higher micromolar range.

1. Introduction

An intensive search for drugs effective in chemotherapy of viral infections and/or various cancers has been under way for decades. The idea of structural modifications of nucleosides and nucleotides gained interest fairly early and appeared fruitful supplying a wide variety of marketed compounds such as ribavirin, zidovudine, adefovir and many others (Fig. 1). In general, the modifications included replacements of the phosphate P(O)—O—C bond for the non-hydrolysable phosphonate P(O)—C linkage, a furanose ring for other heterocyclic or even acyclic fragments or natural nucleobases for unnatural, substituted heteroaromatic or even homoaromatic systems. Several functionalities have been tried as linkers and aliphatic chains as well as 3- to 6-membered aliphatic and aromatic homo- and heterocyclic systems exemplify a long list of examples [1—4].

Among commonly applied linkers a 1,2,3-triazole ring is of special interest since it is extremely easily to prepare by a 1,3-dipolar cycloaddition and biological activity of many 1,2,3-triazole derivatives has been recognised (Fig. 2). The idea of retaining the natural nucleobases with simultaneous introduction of the

functionalised 1,2,3-triazole unit into a furanose ring led to compounds 1 and 2 which showed an antiviral activity [5,6]. On the other hand 2',3'-diethanethio-2',3',5'-trideoxy-5'-triazolonucleosides 3 displayed antitumour activity [7]. Recently, Kim et al. designed novel 1,2,3-triazole-appended C5-modified nucleosides 4 and their anticancer activity was demonstrated [8,9]. Various acyclonucleosides [10,11] and acyclonucleoside phosphonates [12] containing a 1,2,3-triazole unit were obtained from N-propargyl nucleobases and their antiviral activity was evaluated. Among them, pyrimidine- and purine-containing derivatives 5 and 6 appeared to be the most potent so far and exhibited anti-HCV activity (IC50 values of 16 µM) without any cytotoxicity at a concentration up to $100 \mu M$. On the basis of a similar idea, novel 1,2,3-triazole nucleosides 7 linked to DNA nucleobases as a recognition element have been synthesised and their antiviral activity was evaluated [13].

Recently, we succeeded in the synthesis of *N*-substituted *C*-phosphorylated nitrone **8** [14] and its application in the 1,3-dipolar cycloaddition with vinyl acetate was described [15]. Furthermore, the usefulness of C5-acetoxyisoxazolidines **9** as precursors in the synthesis of isoxazolidine nucleoside analogues **10** has recently been demonstrated (Scheme 1) [15,16].

In continuation of these efforts, a novel class of 1,2,3-triazole-containing isoxazolidine nucleosides 11 (Scheme 2) was designed. Although glycosyl as well as furanosyl azides have commonly

been used in a direct synthesis of substituted 1,2,3-triazoles [13,17–20], to the best of our knowledge isoxazolidine analogues of 1-azidofuranose remain unknown. Herein, we wish to report the efficient synthesis of 5-azidoisoxazolidines 12 from 5-acetoxyisoxazolidines 9 and further transformation of the azides 12 into the respective nucleoside mimetics 11. The aim of this study was the preparation of a small library of nucleotide analogues 11 which was based on the idea of replacing of a furanose ring by an isoxazolidine system and introduction of a 1,2,3-triazole linker between isoxazolidine and the respective purine or pyrimidine nucleobase or other aromatic function as a nucleobase replacer (Scheme 2).

2. Results and discussion

2.1. Chemistry

A 9:1 mixture of *trans*- and *cis*-5-acetoxyisoxazolidines **9a** and **9b** was obtained from *N*-methyl-*C*-phosphorylated nitrone **8** and vinyl acetate as previously described [21]. This mixture was

immediately treated with TMSN₃ in the presence of SnCl₄ as a catalyst to give 5-azidoisoxazolidines **12** and **13** in a \sim 1:1 ratio (Scheme 3) [22]. They were cleanly separated on a silica gel column into the less polar diastereoisomer **13** (50%) and more polar **12** (46%).

Since almost an equimolar mixture of both anomeric azides 12 and 13 was detected in a crude product, the replacement of the acetoxy group at C5 with an azide function occurred via the formation of the respective oxonium intermediate. Under these circumstances the nucleophile can attack both faces of the iso-xazolidinium ion to form the azides 12 and 13 as a ca. 1:1 anomeric mixture.

The relative configurations in the diastereoisomeric iso-xazolidines **12** and **13** were established based on 1 H and 13 C NMR spectroscopic data [23,24]. Analysis of vicinal coupling constants extracted from the spectra of the isomer **12** [$J(H_3-H_{4\alpha})=6.8$ Hz, $J(H_3-H_{4\beta})=10.8$ Hz, $J(H_{4\alpha}-P)=4.0$ Hz, $J(H_{4\beta}-P)=17.0$ Hz, $J(H_{4\alpha}-H_5)=0.8$ Hz, $J(H_{4\beta}-H_5)=5.3$ Hz and J(CCCP)=10.3 Hz] shows that the isoxazolidine ring exists in the single ^{4}E conformation. In this conformation the $P(O)(OEt)_{2}$ and

azido groups occupy the pseudoequatorial and pseudoaxial positions, respectively (Fig. 3) and thus reveal the *trans* relationship of H_3 and H_5 . On the other hand, from the NMR spectra of the isoxazolidine **13** the following couplings were calculated: $J(H_3-H_{4\alpha})=9.3$ Hz, $J(H_3-H_{4\beta})=9.1$ Hz, $J(H_{4\alpha}-P)=4.8$ Hz, $J(H_{4\beta}-P)=17.0$ Hz, $J(H_{4\alpha}-H_5)=7.5$ Hz, $J(H_{4\beta}-H_5)=2.4$ Hz and J(CCCP)=10.3 Hz. On the basis of these values, a preferred E_3 conformation having the diethoxyphosphoryl and azido groups in equatorial and pseudoequatorial positions was established (Fig. 3). At the same time, the *cis* relationship of the substituents at C3 and C5 in **13** was unambiguously proved.

Next the 1,3-dipolar cycloadditions of the 5-azidoisoxazolidines 12 and 13 with propargylated nucleobases and selected ethynyl aryls were examined (Scheme 4, Table 1). Because we were interested in the formation of single regioisomers of C4'-substituted 1,2,3-triazoles, all reactions were carried out with equimolar amounts of the respective dipolarophiles 14 using Cu(I) as a catalyst, according to the procedure described by Sharpless [25,26]. Indeed, 5-azidoisoxazolidin-3-yl-3-phosphonate *trans*-12 was cleanly transformed into C4'-substituted 1,2,3-triazoles *trans*-15 in good to excellent yields, whereas from *cis*-13 and the respective alkynes 14, isoxazolidines *cis*-16 were produced exclusively. In all cycloadditions no epimerization at C5 in the isoxazolidine ring was observed.

Additional evidence supporting our configurational assignments in the azidoisoxazolidines 12 and 13 comes from the comparison of the ¹H and ¹³C NMR spectroscopic data of the respective (1,2,3-triazol-1-yl)isoxazolidines 15 and 16. Based on the vicinal couplings $[J(H_3-H_{4\alpha})=6.8-6.9 \text{ Hz}, J(H_3-H_{4\beta})=$ 10.5–11.1 Hz, $J(H_{4\alpha}-P) = 4.5-6.8$ Hz, $J(H_{4\beta}-P) = 16.8-71.7$ Hz, $J(H_{4\alpha}-H_5) = 1.2-1.8 \text{ Hz}, J(H_{4\beta}-H_5) = 6.6-6.9 \text{ Hz} \text{ and } J(CCCP) =$ 9.4–10.5 Hz] observed in the ¹H and ¹³C NMR spectra of the isoxazolidines **15** it was concluded that they exist in the ⁴E conformation, the same as observed for the azidoisoxazolidine 12 (Fig. 4). On the other hand, the preferred E_3 conformation for all (1,2,3triazol-1-yl)isoxazolidines 16 was established based on the vicinal coupling constants derived from their NMR spectra $[J(H_3-H_{4\alpha})=$ 9.0-9.9 Hz, $J(H_3-H_{4\beta}) = 8.1-9.0 \text{ Hz},$ $J(H_{4\alpha}-P) = 5.4-6.0 \text{ Hz},$

2.2. Antiviral and cytostatic evaluation

All (1,2,3-triazol-1-yl)isoxazolidines trans-15 and cis-16 were evaluated for inhibitory activity against a wide variety of DNA and RNA viruses, using the following cell-based assays: (a) human embryonic lung (HEL) cells: herpes simplex virus-1 (KOS), herpes simplex virus-2 (G), herpes simplex virus-1 (TK⁻ KOS ACV^r), vaccinia virus and vesicular stomatitis virus, cytomegalovirus (AD-169 strain and Davis strain) and varicella-zoster virus (TK⁺ VZV strain Oka, and TK- VZV strain 07/1); (b) Vero cell cultures: parainfluenza-3 virus, reovirus-1, Sindbis virus, Coxsackie virus B4, Punta Toro virus; (c) HeLa cell cultures: vesicular stomatitis virus, Coxsackie virus B4 and respiratory syncytial virus; (d) MDCK cell cultures: influenza A virus (H1N1 and H3N2) and influenza B virus; (e) CrFK cell cultures: feline herpes virus (FHV) and feline corona virus (FIPV) and (f) CEM cell cultures: human immunodeficiency virus type 1 (HIV-1) and HIV-2. Ganciclovir, cidofovir, acyclovir, brivudin, (S)-9-(2,3-dihydroxypropyl)adenine [(S)-DHPA], oseltamivir and ribavirin were used as the reference compounds. The antiviral activity was expressed as the EC50: the compound concentration required to reduce virus plaque formation (VZV) by 50% or to reduce virus-induced cytopathogenicity by 50% (other viruses). Unfortunately, no inhibitory activity against any virus was detected for the evaluated compounds at 250 µM.

The cytotoxicity of the tested compounds towards the uninfected host cells was defined as the minimum compound concentration (MCC) that caused a microscopically detectable alteration of normal cell morphology. The 50% cytostatic concentration (CC₅₀), causing a 50% decrease in cell proliferation was determined against murine leukaemia L1210, human lymphocyte CEM, human cervix carcinoma HeLa and human lung fibroblast HEL cells. None of the tested compounds affected cell morphology of HEL, HeLa, Vero, MDCK and CrFK cells at concentrations up to 100 µM. However, several compounds (*trans*-15f-j and *cis*-16f-j) were able to inhibit

with fluorine. The aromatic fragments of these compounds fulfil the requirements to be considered as "nonpolar nucleoside isosteres" [27].

3. Conclusions

Azidation of a 9:1 mixture of *trans*- and *cis*-5-acetoxy-2-methylisoxazolidin-3-yl-3-phosphonates with trimethylsilyl azide in the presence of SnCl₄ gave an easily separable 1:1 mixture of diethyl 5-azido-2-methylisoxazolidin-3-yl-3-phosphonates *trans*-12 and *cis*-13. A series of 1,2,3-triazole-containing isoxazolidin-3-yl-3-phosphonates was obtained in good to excellent yields from azides *trans*-12 and *cis*-13 via 1,3-dipolar cycloaddition with the respective propargylated nucleobases and ethynyl aryls.

The relative configuration in the 5-azidoisoxazolidines *trans*-12 and *cis*-13 as well as the 1,2,3-triazolyl cycloadducts *trans*-15 and *cis*-16 was established based on the conformational analysis using vicinal coupling constants extracted from ¹H and ¹³C NMR spectra.

All synthesised *trans*- and *cis*-(1,2,3-triazolyl)isoxazolidinephosphonates *trans*-**15** and *cis*-**16** were evaluated against a broadspectrum of viruses but found not active at 250 μ M. The unsubstituted and fluoro-substituted phenyl derivatives proved slightly cytostatic (middle to higher micromolar range: 40–250 μ M).

4.1. Chemistry

The 1H NMR spectra were taken in CDCl $_3$ or C_6D_6 on the Varian Mercury-300 spectrometer with TMS as an internal standard. The ^{13}C NMR spectra were recorded for CDCl $_3$ solutions on a Varian Mercury-300 machine at 75.5 MHz. The ^{31}P NMR spectra were taken in CDCl $_3$ or C_6D_6 on Varian Mercury-300 at 121.5 MHz.

IR spectra were measured on an Infinity MI-60 FT-IR spectrometer. Melting points were determined on a Boetius apparatus and are uncorrected. Elemental analyses were performed by the

Microanalytical Laboratory of this Faculty on Perkin—Elmer PE 2400 CHNS analyser.

4.1.1. Synthesis of 5-azidoisoxazolidines 12 and 13

To a solution of a 9:1 mixture of 5-acetoxyisoxazolidines **10** and **11** (3.384 g, 12.03 mmol) in dry methylene chloride (40 mL) trimethylsilyl azide (3.97 mL, 30.08 mmol) was added at 0 °C under argon followed by SnCl₄ (0.704 mL, 6.02 mmol). The reaction mixture was stirred at this temperature for 12 h and then saturated aqueous NaHCO₃ (70 mL) was added at 0 °C. After stirring for 30 min at this temperature organic phase was separated, and an aqueous layer was extracted with methylene chloride (4 × 20 mL). The combined organic layers were washed with saturated aqueous NaHCO₃ (2 × 20 mL), dried over MgSO₄, filtered and solvent was removed under reduced pressure. Purification on a silica gel column with toluene:isopropanol (200:1 and then 100:1, v/v) gave azidoisoxazolidine **13** (1.587 g, 50%) and azidoisoxazolidine **12** (1.468 g, 46%), both as colourless oils.

4.1.2. General procedure for the synthesis of (1,2,3-triazolyl) isoxazolidines **15** and **16**

To a solution of the azidoisoxazolidine **12** or **13** (1.00 mmol) in *tert*-butanol (0.5 mL), $CuSO_4 \cdot 4H_2O$ (0.10 mmol) in water (1 mL) was added followed by sodium ascorbate (0.20 mmol) and the respective alkyne **14** (1.00 mmol). The reaction mixture was stirred at room temperature for 48 h, concentrated and co-evaporated with

ethanol (3×10 mL). The residue was dissolved in chloroform (10 mL), dried over MgSO₄, filtered through a pad of Celite and the solution was evaporated under reduced pressure. The crude product was purified on a silica gel column with chloroform:methanol (from 100:1 to 20:1, v/v) as eluent.

4.2. Antiviral activity assays

The antiviral assays [except anti-human immunodeficiency virus (HIV) assays] were based on inhibition of virus-induced cytopathicity in HEL [herpes simplex virus type 1 (HSV-1), HSV-2 (G), vaccinia virus and vesicular stomatitis virus], Vero (parainfluenza-3, reovirus-1, Sindbis, Coxsackie B4, and Punta Toro virus), HeLa (vesicular stomatitis virus, Coxsackie virus B4, and respiratory syncytial virus), MDCK (influenza A (H1N1 and H3N1) and influenza B virus) or CrFK (feline herpes virus; feline corona virus (FIPV)) cell cultures. Confluent cell cultures in microtiter 96well plates were inoculated with 100 cell culture inhibitory dose-50 (CCID₅₀) of virus (1 CCID₅₀ being the virus dose to infect 50% of the cell cultures) in the presence of varying concentrations (250, 50, 10, ... μM) of the test compounds. Viral cytopathicity was recorded as soon as it reached completion in the control virusinfected cell cultures that were not treated with the test compounds. The methodology of the anti-HIV assays was as follows: human CEM ($\sim 3 \times 10^5$ cells/cm³) cells were infected with 100 CCID₅₀ of HIV-1(III_B) or HIV-2(ROD)/mL and seeded in 200 μL wells of a microtiter plate containing appropriate dilutions of the test compounds. After 4 days of incubation at 37 °C, HIV-induced CEM giant cell formation was examined microscopically.

4.3. Cytostatic activity assays

Murine leukaemia L1210, human T-lymphocyte CEM, human cervix carcinoma (HeLa) and human lung fibroblast (HEL) cells were suspended at 300,000–500,000 cells/mL of culture medium, and 100 μ L of a cell suspension was added to 100 μ L of an appropriate dilution of the test compounds in wells of 96-well microtiter plates. After incubation at 37 °C for two (L1210) or three (CEM, HeLa, HEL) days, the cell number was determined using a Coulter counter. The IC50 was defined as the compound concentration required to inhibit cell proliferation by 50%.
